(57) **ABSTRACT**

A machine tool with lathe tool and milling cutter includes a machine support, a worktable, a moving device, a lathe feeding mechanism and a milling feeding mechanism. The worktable is positioned on the machine support. The moving device is slidably assembled to the machine support along a first direction and located above the worktable. The lathe feeding mechanism and the milling feeding mechanism are slidably assembled to the moving device along a second direction perpendicular to the first direction. The lathe feeding mechanism includes a feeding assembly and a lathe tool connected to the feeding assembly. The feeding assembly is configured for driving the lathe tool to move along a third direction substantially perpendicular to the first and second direction reciprocally, the milling feeding mechanism includes a milling cutter and is configured for driving the milling cutter to move along the third direction.

MACHINE TOOL WITH LATHE TOOL AND MILLING CUTTER

CROSS-REFERENCE TO RELATED APPLICATIONS

This application claims all benefits accruing under 35U.S.C. §119 from China Patent Application No. 201210554105.2, filed on Dec. 19, 2012, in the China Intellectual Property Office, the disclosure of which is incorporated herein by reference. The application is also related to co-pending applications entitled, “METHOD FOR MACHINING METALLIC MEMBER USING LATHING AND MILLING” (application Ser. No. 14/070,671); “METHOD FOR MACHINING METALLIC MEMBER USING LATHING AND MILLING” (application Ser. No. 14/070,722); “MACHINE CONTROL SYSTEM EMPLOYING LATHE TOOL AND SCRAPING CUTTER” (application Ser. No. 14/070,728); “MILLING METHOD FOR MACHINING METALLIC MEMBER” (application Ser. No. 14/070,736).

BACKGROUND

1. Technical Field

The present disclosure generally relates to a machine tool, and particularly, to a machine tool with a lathe tool and a milling cutter.

2. Description of the Related Art

An electronic device, such as a tabletop computer or a mobile phone, employs a metallic member as a housing. The metallic member includes a top portion and a peripheral sidewall extending from a peripheral edge of the top portion. The top portion has a greater surface area than that of the peripheral sidewall. The peripheral sidewall has four side surfaces arranged in order and four corners each connecting two adjacent surfaces. In related manufacturing fields, if a milling process is employed to machine the metallic member, some tracks may occur on the top portion that has been milled because of intermittent contact and interrupted milling of the milling cutter. Then a polishing process needs to be applied to achieve a better appearance. Thus the efficiency of the milling process is reduced. If a lathe process is adapted to machine the metallic member, it may be difficult to tool a surface which is not made for rotating. In addition, the lathe is not suitable to machine the peripheral sidewalls because of the four corners of the peripheral sidewall. Thus a number of additional machining processes must be added to machine the metallic member.

Therefore, there is room for improvement within the art.

BRIEF DESCRIPTION OF THE DRAWING

The components in the drawings are not necessarily drawn to scale, the emphasis instead placed upon clearly illustrating the principles of the present disclosure. Moreover, in the

2

drawings, like reference numerals designate corresponding parts throughout the several views.

FIG. 1 is an isometric view of a first embodiment of a machine tool equipped with a lathe feeding mechanism and a milling feeding mechanism, and a worktable.

FIG. 2 is an exploded, isometric view of the machine tool of FIG. 1.

FIG. 3 is a partial, exploded, isometric view of the lathe feeding mechanism and the milling feeding mechanism of FIG. 2.

FIG. 4 is an exploded, isometric view of the lathe feeding mechanism of FIG. 3.

FIG. 5 is an isometric view of a metallic member to be machined.

FIG. 6 is a sectional view of the metallic member of FIG. 5, taken along line VI-VI of FIG. 5.

FIG. 7 is a schematic view of a second embodiment of the machine tool with a part thereof being removed.

DETAILED DESCRIPTION

FIGS. 1 and 2 show a first embodiment of a machine tool **100** adapting a method for machining a metallic member **300** (see FIG. 5). The machine tool **100** includes a machine support **10**, a worktable **20**, a moving device **30**, a lathe feeding mechanism **40**, a milling feeding mechanism **50**, and a controller **60**. The worktable **20** holds a workpiece in place and is supported by the machine support **10**. The moving device **30** is movably positioned on the machine support **10** above the worktable **20**. The lathe feeding mechanism **40** and the milling feeding mechanism **50** are arranged side by side and slidably mounted on the moving device **30**. The controller **60** is electrically connected to the worktable **20**, the moving device **30**, the lathe feeding mechanism **40**, and the milling feeding mechanism **50** for controlling the machine tool **100**. Under the control of the controller **60**, the moving device **30** can be driven to move with the lathe feeding mechanism **40** and the milling feeding mechanism **50**, such that the lathe feeding mechanism **40** and the milling feeding mechanism **50** can be driven three-dimensionally along Cartesian coordinates, that is, along the X, the Y, and the Z axes.

The machine support **10** includes a base **11** and a pair of support bodies **13** positioned on the base **11**. The pair of support bodies **13** is parallel to each other and arranged apart from each other. Each support body **13** includes a first sliding rail **131** on a surface away from the base **11**. In the illustrated embodiment, the first sliding rail **131** extends substantially parallel to the X-axis (a first direction).

The worktable **20** is rotatably positioned on the base **11** between the two support bodies **13**. The worktable **20** includes a pair of mounting bases **21**, a first rotating member **23**, a rotating shaft **25**, and a second rotating member **27**. The pair of mounting bases **21** is located in the middle portion of the base **11**, in parallel. The pair of mounting bases **21** is located between the two support bodies **13**. The first rotating member **23** is mounted on one mounting base **21**. The rotating shaft **25** interconnects the first rotating member **23** and the other one mounting base **21**. The first rotating member **23** is capable of rotating the rotating shaft **25** around an α axis. The α axis is parallel to the Y-axis but not co-linear (a second direction). The second rotating member **27** is positioned on a middle portion of the rotating shaft **25**, and capable of rotating the metallic member **300** placed thereupon around an β axis. The β axis is parallel to the Z-axis (a third direction) but not co-linear. The first rotating member **23** and the second rotating member **27** are electrically connected to the controller **60**.

In the illustrated embodiment, the first rotating member 23 and the second rotating member 27 are direct drive motors.

The moving device 30 is slidably mounted on the pair of support bodies 13 and located above the worktable 20. The moving device 30 includes a cross beam 31, a pair of sliding bases 33, a pair of first driving mechanisms 35, and a second driving mechanism 37. The extending direction of the cross beam 31 is substantially parallel to the Y-axis. Opposite ends of the cross beam 31 are slidably positioned on the support bodies 13. The cross beam 31 includes a pair of second sliding rails 311 positioned on a side surface thereof and extending substantially parallel to the Y-axis. The pair of sliding bases 33 is installed on the opposite ends of the cross beam 31 to slidably connect with the first sliding rail 131. The first driving mechanism 35 is mounted on a surface of the sliding base 33 away from the cross beam 31 and located adjacent to an end of the first sliding rail 131. The pair of first driving mechanisms 35 is employed to drive the cross beam 31 to move along the X-axis direction.

The second driving mechanism 37 is mounted on the cross beams 31 to drive the lathe feeding mechanism 40 and the milling feeding mechanism 50 to move along the second sliding rails 311. The first driving mechanism 35 and the second driving mechanism 37 are electrically connected to the controller 60. In the illustrated embodiment, the first driving mechanisms 35 and the second driving mechanism 37 are linear motors with wonderful performance. In other embodiments, the first driving mechanisms 35 and the second driving mechanism 37 may be other drivers, such as hydraulic cylinders or rams. The number of the first driving mechanisms 35, and the second driving mechanism 37 may be set according to the application.

FIGS. 3 to 4 show the lathe feeding mechanism 40 slidably positioned on the cross beams 31. The lathe feeding mechanism 40 includes a sliding saddle 41 (see FIG. 2), a mounting seat 43, a tool holder 45, a feeding assembly 47, and a lathe tool 49. The sliding saddle 41 is assembled to the cross beams 31 and movably engages with the pair of second sliding rails 311. The second driving mechanism 37 slides along the Y-axis direction together with the lathe feeding mechanism 40 and the milling feeding mechanism 50 to drive the sliding saddle 41. The sliding saddle 41 is equipped with four guiding rails 413 extending along the Z-axis direction. The four guiding rails 413 are divided in two sets spaced from each other by two-type. The sliding saddle 41 further includes a mounting block 415 adjacent to the base 11. The mounting block 415 is located between the two sets of guiding rails 413. The mounting seat 43 is assembled to the sliding saddle 41 and spaced from the four guiding rails 413.

The mounting seat 43 includes a frame 431 and two mounting boards 433 assembled to opposite sides of the frame 431. The frame 431 includes a first side wall 4311 and a second side wall 4313. The first side wall 4311 and the second side wall 4313 are positioned substantially parallel to each other and cooperatively define a receiving space 4315. The first side wall 4311 is connected with the sliding saddle 41. Two separate guiding portions 4317 protrude from an inner surface of the first side wall 4311 facing the second side wall 4313 and extend substantially parallel to the Z-axis. A through groove 4318 is defined in the second side wall 4313 and extends along a direction substantially parallel to the Z-axis corresponding to the guiding portions 4317. Two sliding portions 4319 protrude from an outer surface of the second side wall 4313 at two sides of the through groove 4318. In the illustrated embodiment, the sliding portions 4319 are sliding rails, and the frame 431 is integrally formed. The two mounting boards 433 are installed on two opening sides of the frame

431. Each mounting board 433 is connected substantially perpendicularly to the first side wall 4311 and the second side wall 4313 to close the two opening sides of the frame 431.

The tool holder 45 slidably connects with the mounting seat 43. The tool holder 45 is substantially "T" shaped, and includes a main body 451 and a sliding board 453 protruding substantially perpendicularly from the main body 451. The main body 451 is a bar of material tapering at both ends, and positioned outside of the mounting seat 43. Two distanced holding portions 4511 are positioned on a surface of the main body 451 facing the sliding board 453. The two holding portions 4511 slidably engage with the pair of sliding portions 4319 of the mounting seat 43. The sliding board 453 passes through the through groove 4318 and is slidably assembled to the two guiding portions 4317, dividing the receiving space 4315 into two parts.

The feeding assembly 47 is mounted in the mounting seat 43, and includes two drivers 471 electrically connected to the controller 60. The two drivers 471 are capable of driving the tool holder 45 into a reciprocating motion at a high speed along the direction of the Z-axis, relative to the guiding portions 4317 and the sliding portions 4319. The two drivers 471 are received in the receiving space 4315 and are positioned on two sides of the sliding board 453. In the illustrated embodiment, the drivers 471 are linear motors. Each driver 471 includes a forcer 4711 and a stator 4713. Each forcer 4711 is fixed to a surface of each of the mounting boards 433. The sliding board 453 is positioned between the two forcers 4711. The two stators 4713 are positioned on the opposite surfaces of the sliding board 453. In other embodiments, the number of drivers 471 may be set according to application. For example, the two drivers 471 can replace a single driver with more power, or three or more drivers can be positioned to drive the tool holder 45 to maximize the available power, and the assembly of the drivers is simpler.

The lathe tool 49 is fastened to the main body 451 of the tool holder 45 adjacent to the base 11.

The milling feeding mechanism 50 includes a linear driving assembly 53, a linking board 54, a rotatable driving member 55 and a milling cutter 57. The linear driving assembly 53 includes a driving member 531, a screw leading rod 533, and a nut 535. The driving member 531 is mounted on the sliding saddle 41 above the cross beam 31. The screw leading rod 533 interconnects the driving member 531 and the mounting block 415. The nut 535 is sleeved on the screw leading rod 533 and engages with the screw leading rod 533. The linking board 54 is slidably assembled to the two sets of guiding rails 413 and fixed to the nut 535. The rotatable driving member 55 is assembled to a side surface of the linking board 54 opposite to the screw leading rod 533. The milling cutter 57 is mounted on an end of the rotatable driving member 55 adjacent to the base 11.

The driving member 531 is capable of rotating the screw leading rod 533 and driving the linking board 54, with the rotatable driving member 55, and the milling cutter 57 to slide along Z-axis direction. The rotatable driving member 55 is capable of rotating the milling cutter 57 milling the metallic member 300. The milling cutter 57 is driven by the cross beam 31 to move along the X-axis direction or the Y-axis direction, and driven by the linear driving assembly 53 to move along Z-axis direction.

In assembly, the worktable 20 is positioned between the two support bodies 13. The cross beam 31 is installed on the two support bodies 13 via the pair of sliding bases 33. The pair of first driving mechanisms 35, and the second driving mechanism 37 are mounted on the base 11 and the cross beam 31, respectively. The lathe feeding mechanism 40 and the

5

milling feeding mechanism 50 are mounted to the cross beam 31 side by side. The worktable 20, the moving device 30, the lathe feeding mechanism 40, and the milling feeding mechanism 50 are electrically connected to the controller 60.

FIGS. 5 and 6 show that the metallic member 300 to be machined is a housing of a tablet computer or a mobile phone. The metallic member 300 is substantially rectangular, and includes a top portion 301 and a peripheral sidewall 303 extending from a peripheral edge of the top portion 301. The top portion 301 has a non-symmetrical curved surface with a relatively greater surface area than that of the peripheral sidewall 303. In the embodiment, the peripheral sidewall 303 has four side surfaces 3031 arranged in order and adjacent two of the four side surfaces 3031 are connected by a corner 3033. The four side surfaces 3031 are substantially planar surfaces, each corner 3033 interconnects two adjacent side surfaces 3031.

When in work, the metallic member 300 is placed and held on the worktable 20. The worktable 20 drives the metallic member 300 to rotate. In the embodiment, the metallic member 300 is driven by the second rotating member 27 to rotate around the β axis. The lathe feeding mechanism 40 drives the lathe tool 49 to reciprocate the top portion 301 of the metallic member 300 at a high frequency. In detail, first, the pair of first driving mechanisms 35 drive the cross beam 31 to slide along the X-axis, and the second driving mechanism 37 drives the lathe feeding mechanism 40 to move along the Y-axis, until the lathe tool 49 arrives at an original position above the worktable 20 for machining. In the embodiment, the original position is located above a middle portion of the metallic member 300. Finally, the second rotating member 27 drives the metallic member 300 to rotate around the β axis, simultaneously, the feeding assembly 47 drives the lathe tool 49 to move backwards and forwards at a high speed along the Z-axis according to the depth of cutting required for each machining portion of the top portion 301 to machine the metallic member 300 circumferentially. The moving speed of the lathe tool 49 and the rotating speed of the second rotating member 27 is set according to an application. A track of the lathe tool 49 projected to a top of the metallic member 300 is a spiral curve.

The lathe tool 49 moves away from the metallic member 300. The milling feeding mechanism 50 drives the milling cutter 57 to rotate and resist the peripheral sidewall 303 of the metallic member 300. In detail, firstly, the pair of first driving mechanisms 35 drives the cross beam 31 to slide along the X-axis, and the second driving mechanism 37 drives the lathe feeding mechanism 40 to move along the Y-axis, such that the milling cutter 57 arrives at a position above an end of one side surface 3031 of the peripheral sidewall 303. Second, the linear driving assembly 53 drives the milling cutter 57 to slide along the two sets of guiding rails 413 until the milling cutter 57 resists the peripheral sidewall 303 of the metallic member 300. Finally, the rotatable driving member 55 drives the milling cutter 57 to rotate, thereby milling the side surface 3031 and the corner 3033. The milling feeding mechanism 50 remains still, the worktable 20 rotates the metallic member 300 to enable the milling feeding mechanism 50 to mill the metallic member 300 along the predetermined path. The rotatable driving member 55 controls a feed of the milling cutter 57 relative to the metallic member 300 along the Z-axis direction. When finished, the moving device 30 returns to an original position, and the metallic member 300 is taken out. In another embodiment, the metallic member 300 is firmly fixed, the milling feeding mechanism 50 automatic mills the metallic member 300 along a predetermined path. In addition, when a particular portion of the metallic member 300 is to be

6

machined, the rotating member 25 rotates the metallic member 30 along α axis, the second rotating member 27 rotates the metallic member 300 along the β axis, thereby positioning the metallic member 300 in a particular position for machining.

The lathe feeding mechanism 40 is capable of moving backwards and forwards along the Z-axis toward the metallic member 300 at a high speed, thereby a non-interrupted machining process is achieved, the finish of the top portion 301 is enhanced, additional surface processing to the top portion is omitted. The rotatable driving member 55 is capable of driving the milling cutter 57 to rotate, thereby milling the peripheral sidewall 303. The metallic member 300 can be machined by the lathe tool 49 and the milling cutter 57 without disassembly/assembly to adapt to different machines, thereby enhancing a position accuracy, a machining efficiency and a yield of the metallic member 300. Because the moving device 30 is capable of moving the lathe feeding mechanism 40 and the milling feeding mechanism 50 along the X/Y directions, the lathe tool 49 and the milling cutter 57 can be moved along Z direction, the worktable 200 is capable of driving the metallic member 300 to rotate along the .alpha. axis and the .beta. axis, such that the machining process is more convenient and the machining efficiency is enhanced.

The machine tool 100 may merely be employed to lathe or mill the metallic member 300. The lathe tool 49 may not only machine the top portion 301, but also machine workpiece in other shapes. The milling feeding mechanism 50 may not only mill the peripheral sidewall 303, but also mill holes or grooves on the metallic member 300. The outer surface of the metallic member 300 only needs to be machined by the milling feeding mechanism 50 to receive a finished surface.

The sliding saddle 41, the mounting seat 43, the tool holder 45 may be omitted. In other embodiments, the feeding assembly 47 may be substituted with other driving assemblies assembled to the pair of second guiding rails 311. The driving assembly is capable of directly reciprocating the lathe tool 49 along the Z direction at a high speed.

The milling feeding mechanism 50 mills the peripheral sidewall 303 of the metallic member 300 before the lathe feeding mechanism 40 machines the top portion 301. The milling feeding mechanism 50 may not be assembled to the sliding saddle 41, but could be assembled to a sliding plate (not shown) slidably mounted on the pair of second guiding rails 311, such that the lathe feeding mechanism 40 and the milling feeding mechanism 50 may be controlled independently.

The driving member 531, the screw leading rod 533, and the nut 535 may be substituted by other driving assembly, such as a linear cylinder. The linear cylinder is assembled to the pair of second guiding rails 311, the rotatable driving member 55 is mounted on an output shaft of the linear cylinder. Accordingly, the linking board 54 of the milling feeding mechanism 50 may be omitted.

In some embodiments, the worktable 20 may only include the second rotating member 27, the second rotating member 27 is assembled to the base 11, and rotates around the β axis only. The worktable 20 may be a multi-axis worktable, capable of rotating the metallic member 300 along a plurality of axis to enable a multi-workstations machining process.

FIG. 7 shows a second embodiment of machine tool 200 for machining the metallic member 300. The machine tool 200 is similar to the machine tool 100 in structure, a sliding saddle 41a is slidably assembled to a cross beam 31a, and a second rotating member 27a is mounted on a rotating shaft 25a. The metallic member 300 is placed and held on the second rotating member 27a. The difference between the machine tool

7

100/200 is that, a mounting seat 43a of the machine tool 200 is slidably mounted on the sliding saddle 41 a and capable of sliding along the Z1-axis direction relative to the sliding saddle 41a, and a lathe tool 49a is slidably mounted on the mounting seat 43a.

When the lathe feeding mechanism 40 is to machine the top portion 301 of the metallic member 300, the pair of first driving mechanisms 35 drives the cross beam 31 to slide along the X-axis, and the second driving mechanism 37 drives the lathe feeding mechanism 40 to move along the Y-axis, such that the lathe tool 49a arrives at an original position above the worktable 20 for machining. Then the mounting seat 43a drives the lathe tool 49a to move downward along the Z1-axis to reach a preset position near the middle portion of the metallic member 300. Finally, the feeding assembly 47 drives the lathe tool 49a to reciprocate, cutting at a high speed along the Z-axis according to the depth required for each portion of the top portion 301 machining the rotary metallic member 300 circumferentially. The mounting seat 43a can slide along the Z1-axis to place the lathe tool 49a at the preset position, allowing a reciprocation of the lathe tool 49 relative to the metallic member 300 to be reduced, thereby enhancing a reaction response of the lathe tool 49a.

While the present disclosure has been described with reference to particular embodiments, the description is illustrative of the disclosure and is not to be construed as limiting the disclosure. Therefore, various modifications can be made to the embodiments by those of ordinary skill in the art without departing from the true spirit and scope of the disclosure, as defined by the appended claims.

What is claimed is:

1. A machine tool with a lathe tool and a rotating milling cutter, the machine tool comprising:

a machine support;

a worktable for rotating a workpiece and positioned on the machine support;

a moving device slidably assembled to the machine support so as to slide along a first direction and located above the worktable;

a lathe feeding mechanism slidably assembled to the moving device so as to slide along a second direction perpendicular to the first direction, the lathe feeding mechanism comprising a feeding assembly and the lathe tool, with the lathe tool connected to the feeding assembly, the feeding assembly being configured for driving the lathe tool to move reciprocally along a third direction substantially perpendicular to the first and the second direction, the lathe feeding mechanism further including:

a mounting seat fittingly assembled to a sliding saddle,

the sliding saddle being slidably connected to the moving device so as to slide along the second direction, the mounting seat including a frame including first and second opposed side walls that cooperatively define a receiving space therebetween, wherein a through groove is defined in the second side wall, wherein the lathe tool is mounted to a substantially-T-shaped tool holder, wherein the T-shape of the substantially T-shaped tool holder is formed by a main body and a sliding board, the sliding board extending through the through groove and being slidably engaged, for movement in the third direction, with a guiding portion mounted on the first side wall and within the receiving space, and the main body including a holding portion that is slidably engaged, for movement in the third direction, with a guiding portion mounted on the second side wall; and

8

a milling feeding mechanism slidably assembled to the moving device so as to slide along the second direction, the milling feeding mechanism being adjacent to the lathe feeding mechanism, wherein the milling feeding mechanism comprises the milling cutter and is configured for driving the milling cutter to move along the third direction.

2. The machine tool of claim 1, wherein the feeding assembly is received in the mounting seat, and the milling cutter is slidably mounted on the sliding saddle and adjacent to the mounting seat, and the milling cutter is capable of moving along the third direction relative to the mounting seat.

3. The machine tool of claim 2, wherein the milling feeding mechanism comprises a linear driving assembly and a rotatable driving member, the linear driving assembly is mounted on the sliding saddle, the rotatable driving member is connected to the linear driving assembly, the linear driving assembly drives the rotatable driving member and the milling cutter to move along the third direction and to adjust feed of the milling cutter relative to the workpiece, and the rotatable driving member is capable of driving the milling cutter to rotate.

4. The machine tool of claim 3, wherein the sliding saddle comprises a mounting block, the linear driving assembly comprises a driving member, a screw leading rod, and a nut, the driving member of the linear driving assembly is mounted on the sliding saddle, the screw leading rod interconnects the linear driving assembly driving member and the mounting block, the nut is sleeved on and engages with the screw leading rod, the milling feeding mechanism further comprises a linking board fixed to the nut and slidably engaged with the sliding saddle, and the rotatable driving member is fittingly assembled to the linking board.

5. The machine tool of claim 4, wherein the sliding saddle further comprises two sets of guiding rails, the mounting block is located between the two sets of guiding rails, and the linking board is slidably assembled to each of the two sets of guiding rails.

6. The machine tool of claim 1, wherein the mounting seat comprises a further guiding portion mounted on the first side wall, extending along the third direction, and wherein the tool holder is slidably assembled to each of the guiding portions mounted on the first side wall.

7. The machine tool of claim 6, wherein the sliding board protrudes substantially perpendicularly from the main body, the main body is positioned out of the mounting seat, the sliding board is received in the mounting seat and is slidably assembled to each of the guiding portions that are mounted on the first side wall, and the lathe tool is mounted on the main body.

8. The machine tool of claim 7, wherein the feeding assembly comprises at least one forcer and at least one stator correspondingly located relative to the at least one forcer, the at least one forcer is fixed to the mounting seat, and the at least one stator is positioned on the sliding board.

9. The machine tool of claim 1, wherein the worktable is capable of rotating about an axis parallel to the third direction.

10. The machine tool of claim 1, wherein the worktable comprises a pair of mounting bases, a first rotating member, a rotating shaft, and a second rotating member, the first rotating member is mounted on one of the two mounting bases, the rotating shaft interconnects the first rotating member and another one of the two mounting bases, the second rotating member is positioned on the rotating shaft and is capable of rotating about an axis parallel to the third direction, and the first rotating member is capable of rotating the rotating shaft about an axis parallel to the second direction.

9

11. A machine tool with a lathe tool and a rotating milling cutter, the machine tool comprising:

a machine support comprising:

a base and a pair of support bodies positioned on the base; the machine tool further comprising:

a worktable for rotating a workpiece and positioned on the base between the pair of support bodies;

a moving device comprising a cross beam having opposite ends slidably positioned on the support bodies, the cross beam being capable of sliding along a first direction and located above the worktable;

a lathe feeding mechanism slidably assembled to the cross beam so as to slide along a second direction perpendicular to the first direction, the lathe feeding mechanism comprising the lathe tool and being configured for driving the lathe tool to move reciprocally along a third direction substantially perpendicular to the first and second direction, the lathe feeding mechanism further including:

a mounting seat fittingly assembled to a sliding saddle, the sliding saddle being slidably connected to the cross beam so as to slide along the second direction, the mounting seat including a frame including first and second opposed side walls that cooperatively define a receiving space therebetween, wherein a through groove is defined in the second side wall, wherein the lathe tool is mounted to a substantially T-shaped tool holder, wherein the T-shape of the substantially T-shaped tool holder is formed by a main body and a sliding board, the sliding board extending through the through groove and being slidably engaged, for movement in the third direction, with a guiding portion mounted on the first side wall and within the receiving space, and the main body including a holding portion that is slidably engaged, for movement in the third direction, with a guiding portion mounted on the second side wall; and

a milling feeding mechanism slidably assembled to the cross beam so as to slide along the second direction perpendicular to the first direction, the milling feeding mechanism being adjacent to the lathe feeding mechanism, wherein the milling feeding mechanism comprises the milling cutter and is configured for driving the milling cutter to move along the third direction.

12. The machine tool of claim **11**, wherein the lathe feeding mechanism further comprises a feeding assembly, wherein the feeding assembly is received in the mounting seat, and the lathe tool is slidably mounted on the mounting seat, the milling feeding mechanism is mounted on the sliding saddle adjacent to the mounting seat, and the milling cutter is capable of moving along the third direction relative to the mounting seat.

13. The machine tool of claim **12**, wherein the milling feeding mechanism comprises a linear driving assembly and a rotatable driving member, the linear driving assembly is

10

mounted on the sliding saddle, the rotatable driving member is connected to the linear driving assembly, the linear driving assembly drives the rotatable driving member and the milling cutter to move along the third direction to adjust the feed of the milling cutter relative to the workpiece, and the rotatable driving member is capable of driving the milling cutter to rotate.

14. The machine tool of claim **13**, wherein the sliding saddle comprises a mounting block, the linear driving assembly comprises a driving member, a screw leading rod, and a nut, the driving member of the linear driving assembly is mounted on the sliding saddle, the screw leading rod interconnects the linear driving assembly driving member and the mounting block, the nut is sleeved on and engages with the screw leading rod, the milling feeding mechanism further comprises a linking board fixed to the nut and slidably engaged with the sliding saddle, and the rotatable driving member is fittingly assembled to the linking board.

15. The machine tool of claim **14**, wherein the sliding saddle further comprises two sets of guiding rails, the mounting block is located between the two sets of guiding rails, and the linking board is slidably assembled to the two sets of guiding rails.

16. The machine tool of claim **11**, wherein the mounting seat comprises a further guiding portion mounted on the first side wall, extending along the third direction, and wherein the tool holder is slidably assembled to each of the guiding portions mounted on the first side wall.

17. The machine tool of claim **16**, wherein the sliding board protrudes substantially perpendicularly from the main body, the main body is positioned out of the mounting seat, the sliding board is received in the mounting seat and is slidably assembled to each of the guiding portions mounted on the first side wall.

18. The machine tool of claim **17**, wherein the feeding assembly comprises at least one forcer and at least one stator corresponding to the at least one forcer, the at least one forcer is fixed to the mounting seat, and the at least one stator is positioned on the sliding board.

19. The machine tool of claim **11**, wherein the worktable is capable of rotating about an axis parallel to the third direction.

20. The machine tool of claim **11**, wherein the worktable comprises a pair of mounting bases, a first rotating member, a rotating shaft, and a second rotating member, the first rotating member is mounted on one mounting base, the rotating shaft interconnects the first rotating member and the other one mounting base, the second rotating member is positioned on the rotating shaft and is capable of rotating about an axis parallel to the third direction, and the first rotating member is capable of rotating the rotating shaft about an axis parallel to the second direction.
